Introduction A.1 Motivation Common segmentation problems in brain MRI include segmenting structural abnormalities, white matter lesions, multiple sclerosis lesions, and lesions detected by fluid-attenuated inversion recovery (FLAIR) sequences. We present a combined intensity and prior based segmentation approach for the segmentation of white matter lesions in brain MRI using singular value decomposition. Hence, we introduce a method for segmenting (and aligning) and provides a comparison between three alternative approaches. The first method uses ratio constraint with a scale and rotation invariant cost function, and after a singular value decomposition (SVD) we reduce the number of parameters to be optimized. The second method introduces an additional regularization term for the SVD operation. The third approach represents the boundaries of the lesion as a collection of line segments and aligns and segments the white matter regions by minimizing an energy function that includes the image Gaussian prior term and the image singular value decomposition (SVD) regularization term. A.2 Related work SVD based image segmentation has been described in previous work. For 79a2804d6b
